Arrays in Excel

Definition: An array is a collection of values that Excel can process together in a single formula.

Why Do We Use Arrays?

- To perform calculations on multiple values at once.
- To reduce the need for separate formulas.
- To filter, sort, and extract unique values from data.

Example

Suppose cells A1 to A4 contain 10, 20, 30, and 40.

Formula:
=A1:A4*2

Excel returns:
20, 40, 60, 80

The formula multiplies all values by 2 and displays the results automatically. This feature is available in Excel versions that support dynamic arrays.

Important Array Functions

- FILTER() – Filters data based on a condition.
- SORT() – Sorts values.
- UNIQUE() – Returns unique values.
- SEQUENCE() – Generates a sequence of numbers.

  =SEQUENCE(rows,[columns],[start],[step])

Remember: Arrays allow Excel to work with multiple values together instead of processing each value separately.
